23 Running head: Salmon baby food containing salmon roe

24 **ABSTRACT:** Baby food was formulated from sockeye salmon (puree alone, puree  
25 + chunks, puree + pink roe, puree + pink roe + chunks, puree + red roe, puree +  
26 red roe + chunks). In the first study physical (pH, instrumental color, water  
27 activity) and descriptive sensory (odor, flavor, texture, visual color) characteristics  
28 of the products were determined. Descriptive results indicated that samples  
29 containing roe were lighter than formulations without roe regardless of the type of  
30 roe added. Products containing roe were also less red (by approximately 3 to 4 a\*  
31 units) than formulations without roe regardless of roe type. Visual pink color  
32 followed the same trend. Formulations with roe, both pink and sockeye, were  
33 almost twice as fibrous as formulations without roe. Salmon flavor was stronger in  
34 samples containing roe from sockeye salmon. In a second study, retort processed  
35 samples were stored at room temperature for 6 months. Storage time (6 mo)  
36 affected sweaty, cooked egg, earthy, and ocean odors, and pink and yellow visual  
37 scores. L\* and a\* values of samples without roe appeared to be most stable over the  
38 storage period. The best correlations between visual and instrumental color  
39 occurred between visual cream-brown and L\*, a\*, b\* and chroma values (r = -0.80,  
40 0.75, 0.80 and 0.84, respectively). TBARS values ranged between 0.1 and 0.35 mg  
41 MDA/kg. TBARS values of all samples declined after month 2 then stayed fairly  
42 constant over the remainder of the storage period.

47

## Introduction

48           The salmon industry in Alaska is in transition due to increasing the availability of  
49 cheaper farm-raised salmon. This has resulted in a loss of market share for Alaskan  
50 salmon and a large decrease in total harvest value. In 2007, nearly 500,000 metric tons of  
51 Alaskan salmon valued at 420 million dollars was harvested (Alaska Department of Fish  
52 and Game, 2007).

53           For producers of agricultural commodities to profit, outlets through direct  
54 distribution of fresh products (fish, chicken, etc.) or demand for these raw materials for  
55 further processing by food companies must be continuous. When other new products  
56 enter the market taking away market share, it becomes necessary for individual  
57 commodities to become actively engaged in market expansion. For raw materials  
58 demand to increase, food companies must grow continue to profit, by: (1) expanding into  
59 new geographic markets, (2) taking market share from competitors by increasing market  
60 penetration, or (3) developing new products that can replace those whose profitability is  
61 waning. The current project targets all three in addition to offering a potential new use  
62 for salmon roe.

63           A specific “market need” is a prerequisite to new product success. Salmon is a  
64 good source of the omega-3 fatty acid, docosahexaenoic acid (DHA). The newborn  
65 infant’s brain is 50% DHA, however it is unable to synthesize this compound from alpha-  
66 linolenic acid in sufficient amounts to ensure an adequate supply to the developing neural  
67 tissues. The World Health Organization recommends that infant diets (formulas) provide  
68 40 mg of DHA / kg body weight to provide for the needs of the developing brain

69 provides additional impetus for developing infant foods from roe from cold water fish  
70 such as salmon (FAO, 1994).

71 Salmon roe contain approximately 50-3000 IU/g Vitamin A, 5-25 IU/g Vitamin  
72 D, 10-80 UI/100g of Vitamins B1, B2, and B12, and 10-30 IU/100g Vitamin C (Bledsoe  
73 and others, 2004). Salmon roe contain significantly more DHA and EPA than fish oils  
74 from tuna and sardines and are more oxidatively stable, most likely because of the  
75 phospholipid content (Moriya and others, 2007). Salmon roe can offers a natural source  
76 of Vitamin D which enhances bone development and prevents rickets. Vitamin D is  
77 found naturally in significant quantities only in fatty fish and fish oils, liver and fat from  
78 aquatic mammals, and chicken eggs fed Vitamin D. The American Academy of  
79 Pediatrics has recently doubled the recommended dietary intake of Vitamin D for infants,  
80 children, and adolescents to 400 UI/day (Wagner and Greer, 2008). Further, fish roe  
81 provide high quality protein (Bledsoe and others, 2003) and are a rich source of amino  
82 acids such as glutamic acid, lysine, serine, and aspartic acid (Mol and Turan, 2008).

83 While incorporating roe into baby food products could potentially increase the  
84 nutritive value of these products, retort processing can be expected to alter salmon-based  
85 food products (Kristinsson and others, 2009; Ramamoorthi and others, 2009). Similar to  
86 salmon flesh, roe are heat labile and also undergo irreversible protein denaturation at 70-  
87 80°C resulting in loss or dulling of the characteristic color. The feasibility of roe  
88 inclusion hinges on the sensory quality and stability (shelf life) of the product. The  
89 suitability of roe from red and pink salmon for this application is unknown. This study  
90 examines 6 combinations of retort processed salmon and roe baby food products designed  
91 to meet the FDA definition of a toddler “high meat dinner” (at least 26% salmon; 9 CFR

92 381.117[d]) in terms of sensory characteristics, visually and instrumentally measured  
93 color, pH and water activity.

94

95

## Materials and Methods

96 This experiment was designed as a randomized complete block with six treatment  
97 combinations and four replications. Treatment combinations included baby food  
98 formulations from sockeye salmon (purée, puree + chunks, puree + red row, puree + red  
99 row + chunks, puree + pink row, puree + pink roe + chunks). Physical and sensory  
100 characteristics of the products were determined within 48 h of product manufacture for  
101 the descriptive study. In a second study, storage stability (6 months) based on quality  
102 characteristics was determined

### 103 Sample manufacture

104 Sockeye salmon was chosen for formulation of the base purée to remove the  
105 undesirable characteristics (excessive lightening, off flavor development) found in pink  
106 salmon formulations in an earlier study (DeSantos and others, 2009). Wild sockeye  
107 ("red") salmon (*Oncorhynchus nerka*) were processed by Ocean Beauty Seafoods LLC  
108 (Seattle, WA, U.S.A.). Bone-in fillets (400-600 g) were individually quick-frozen,  
109 shipped (frozen) to the University of Illinois (Urbana-Champaign, IL), and stored at -  
110 28°C until use. Frozen salmon was thawed under controlled conditions (4-6°C in the  
111 dark) for 2 days prior to baby food manufacture. Baby food was manufactured by  
112 combining salmon, water and starch, and roe from red or pink salmon (*Oncorhynchus*  
113 *gorbuscha*) such that 8% of the purée was comprised of salmon roe (Table 1).

114 Thinly-sliced fillets (2-3cm) and salmon roe were cooked for 3 min in boiling  
115 water, and homogenized with a KitchenAid blender (Pro-line, KitchenAide Counter Top  
116 Products, St. Joseph, MO) at “high” setting for 90 s. Organic Corn Starch (National  
117 Starch-Food Innovation, Bridgewater, NJ, U.S.A.) was added during the last 30 s of  
118 blending. The product was hot-filled into glass containers (180 mL; 100 mm height, 65  
119 mm width—Jarden Home Brands, Daleville, Indiana) and closed using two-piece metal  
120 vacuum-sealable lids to yield approximately 170 g of product per container. For chunked  
121 formulations, pre-weighed raw salmon chunks (40-70 mm) were added to base purée at a  
122 ratio of 25% chunks / 75% puree (by wt).

123 Heat penetration studies were conducted with the target of a 12 D reduction of  
124 *Clostridium botulinum*. The temperature distribution during thermal processing was  
125 assessed using temperature probes inserted into the middle and at the bottom of the  
126 containers. The temperature was measured at one min intervals and temperature  
127 distribution was plotted. Based on the heat penetration results and known times to  
128 inactivated *Clostridium sporogenes* SC220-4, the thermal process time was calculated for  
129 the baby food (Lut and others, 1981; Myset, 1985; BAM, 2001; Ocasio, 2008). To build  
130 sufficient pressure in the retort to reach 121 C took 5 min

131 The time was calculated to produce a five log reduction of *C. sporogenes* based  
132 on the time required for samples to attain the required temperature (118-121C) at the cold  
133 point (based on heat penetration studies) plus known times to achieve a 1 log reduction  
134 (BAM, 2001; Ocasio, 2008). Pressure was released over a 13 min. period. Containers of  
135 baby food products were thermally processed at 118-121°C for 55 min in a steam-  
136 jacketed vertical still retort (Model # AA3152, Food Machinery and Chemical Corp.,

137 Hoopeston, IL) then cooled to room temperature by pumping potable water (25°C)  
138 through the retort for 10 min after steam was released.

139

#### 140 **Descriptive analysis**

141       Sensory panelists (21-55 yr; n = 8) who had previous experience with sensory  
142 evaluation of salmon products were trained over four 2-hr sessions. A reference set of  
143 descriptors was provided (Prell and Sawyer 1988) then characteristics of interest were  
144 selected and reference standards determined. Salmon samples and standards were  
145 evaluated such that standards could be assigned locations on the 15-point intensity rating  
146 scale (0 = none; 15 = extreme) for each characteristic (Table 2). Judges evaluated the  
147 visual color of samples using standards shown in Table 3. Unsalted crackers and water  
148 were provided for cleansing the palate between samples. Standards were provided at all  
149 sessions. Samples were capped in 60 mL portion cups, labeled with 3-digit random  
150 numbers, at least one hour before evaluation and heated to an internal temperature of  
151 45°C in a water bath (60°C).

152       All treatment combinations (purée, puree + chunks, puree + red row, puree + red  
153 row + chunks, puree + pink row, puree + pink roe + chunks) were first evaluated for odor  
154 and taste characteristics. Samples were then presented under fluorescent light (GE warm  
155 white, 3013 lux, General Electric, Fairfield, CT, U.S.A.) against a white background.  
156 Visual color was evaluated following odor, taste, and texture evaluations so as to prevent  
157 bias due to visual appearance.

158 **Water activity, pH, viscosity and instrumental color**

159 Water activity ( $a_w$ ) was determined using an AquaLab CX2 meter (Decagon,  
160 Pullman, WA, U.S.A.). The pH was determined by placing the electrode of an Accumet  
161 pH meter (Accumet model 15, Fisher Scientific, Pittsburgh, PA, U.S.A.) directly into  
162 baby food samples (22 °C). Viscosity was determined on the red salmon puree used as  
163 the base for all the babyfood products at 20 rpm using spindle 4 in a Brookfield  
164 Viscometer (Brookfield SP Model LR 99102, Brookfield Engineering Laboratories Inc.,  
165 Middleboro, MA). Instrumental color was determined using a LabScan 6000  
166 spectrophotometer (Hunter Labs, Reston, VA, U.S.A.) Reflectance was determined over  
167 the 400 to 700 nm range using illuminant D65 in order to calculate CIE  $L^*$ ,  $a^*$ , and  $b^*$   
168 values, hue angle ( $\arctan(b^*/a^*)$ ) and chroma ( $[a^{*2} + b^{*2}]^{1/2}$ ) (CIE 1978).

169

170 **Storage study**

171 Samples were formulated and processed as previously described then stored at  
172 room temperature (22°C) in the dark for 6 months. Samples were removed from storage  
173 monthly and evaluated by instrumental, chemical, and sensory means. These samples  
174 were then discarded. Water activity, pH and instrumental color were determined.

175 Sensory judges were trained as previously described to evaluate odor using the  
176 designated sensory terms in Table 2 and the visual color scale shown in Table 3.

177 Thiobarbituric acid reactive substances (TBARS): TBARS were determined after  
178 each month of storage using the cold extraction method described by Miller (1998) based  
179 on the method developed by Witte, Krause, & Bailey (1970). Absorbance was  
180 determined spectrophotometrically (Beckman Coulter DU® 640, Inc., Fullerton, CA,

181 U.S.A.) at 530 nm. Concentration of malondialdehyde (MDA) was calculated from a  
182 standard curve using solutions of tetraethoxypropane (TEP; 0-10 nm MDA/ml). The  
183 equation obtained from the curve was  $y=0.0819 x + 0.0055$  ( $r^2=0.999$ ) where  $y$  is the  
184 absorbance of the sample extract and  $x$  is the concentration of MDA. Malondialdehyde  
185 recovery was computed using the TEP-spiked samples. Each sample was analyzed in  
186 duplicate. Results are expressed as mg malondialdehyde / kg sample.

187 Descriptive data from the first part of the study were treated as a 2 (purée or  
188 chunk) by 3 (no roe, with pink roe, or with sockeye roe) factorial design, and analyzed  
189 using the Mixed Models procedure (SAS, 2002) to determine main effects and  
190 interactions. Effects were considered significant at  $p < 0.05$ . Separation of least square  
191 means (LSM) was achieved using the Tukey-Kramer *post hoc* test for multiple  
192 comparisons. For sensory data, judges were included as a random effect and experiment  
193 replication as a repeated measure. Correlations between instrumental and visual color,  
194 and among sensory odor and flavor scores were made using PROC CORR (SAS 2002).  
195 All results from the Mixed Models are reported as least squares means of the fixed  
196 effects.

197 Instrumental data and TBARS for the storage study were treated as a 2 (puree or  
198 chunk) by 3 (no roe, sockeye or pink roe) by 7 (storage time) factorial design, and  
199 analyzed using the Mixed Models procedure (SAS, 2002) to determine main effects and  
200 interactions. Effects were considered significant at  $p < 0.05$ . Separation of least square  
201 means (LSM) was achieved using the Tukey-Kramer *post hoc* test for multiple  
202 comparisons. Sensory data were analyzed as described for instrumental data with the  
203 inclusion of judges as a repeated measure. Correlations between instrumental and visual

204 color were made using PROC CORR (SAS 2002). All results from the Mixed Models are  
205 reported as least squares means (LSMeans) of the fixed effects, and standard errors of the  
206 mean (SEM) reported for significant measures.

207

## 208 **Results**

### 209 **Characteristics of raw materials**

210 Raw bone-in salmon was 73 - 73.6% moisture, about 1.7% fat, had an L\* value of  
211 67.4, an a\* value of 34.8, b\* value of 36.2, and chroma of 50.2 (data not shown). .

212

### 213 **Descriptive study results**

214 The pH ranged from 6.47 to 6.84 among the six products formulated (data not  
215 shown). Formulations containing pink roe were similar in pH to those without roe (6.7;  
216 SEM=0.02), and were slightly higher than those formulated with sockeye salmon roe  
217 (6.5). The water activity of all treatment combinations was 0.99. The viscosity of the red  
218 salmon puree that was used as the baby food base for all treatments was 3800 cP.  
219 Viscosity of roe-containing samples was above the upper limit of measurement of the  
220 viscometer.

221 There was a significant roe type (red vs pink) by product type (chunk vs puree)  
222 interaction for L\* and a\* values, hue angle, bitter, metallic and mouth-drying flavors and  
223 visual pink color (Table 4). The addition of roe had a direct effect on L\* values of the  
224 puréed baby foods. Samples containing roe had higher L\* values (lighter) than those  
225 without roe (Table 4), regardless of the type of roe added. This lightening may result  
226 from the increase in fat content of the formulation. The fat content of the sockeye salmon

227 puree was about 0.85 g/100g (Brewer 2008) while that of roe-containing samples  
228 contained 1.4 to 2.69 g/100g. Fat content has been shown to affect the color of salmon  
229 products (Christiansen and others, 1995).

230 Products containing roe were also less red (by approximately 3 to 4 a\* units) than  
231 formulations without roe, with no clear difference due to roe source (red versus sockeye).  
232 Visual pink color followed the same trend; judges scored salmon products with roe as  
233 less pink than those without roe, and visual pink scores for base purée (without roe)  
234 averaged at least one unit (on the 15-cm line) higher (pinker) than the chunked product  
235 without roe. Hue angles were lowest (closer to the true red axis of the color scale) for  
236 sockeye salmon purée with neither roe nor chunks, and were similar for all other  
237 products. There was an interaction between roe addition and chunk inclusion for mouth-  
238 drying mouth feel (Table 4). Pureed samples without roe had the lowest mouth-drying  
239 scores scores (2.47-3.48) while the puree with pink roe had the highest (6.05). Metallic  
240 flavor was most prominent in the chunked product containing roe from pink salmon and  
241 lowest in chunked product containing roe from sockeye salmon (Table 4). While the  
242 presence of roe appeared to attenuate the bitter taste, it did not have the same effect on  
243 metallic flavor.

244 Samples without roe were perceived to be more bitter (Table 4). Lawless, Rapacki  
245 and Hayes (2003) reported that tastes associated with calcium chloride were largely  
246 suppressed when calcium was combined with larger organic ions such as lactate,  
247 gluconate or glycerophosphate. It is possible that the addition of roe to the base  
248 formulation moderated the bitter taste detected either through an association of bitter  
249 components with calcium or by attenuating the taste response due to an increase in lipid

250 compounds from the roe (Lawless, Rapacki and Hayes, 2003). Not unexpectedly, bitter  
251 flavor was negatively correlated with sweet flavor ( $r^2 = -0.82$ ; Table 5).

252 Roe from pink salmon is yellow while that from sockeye salmon is a very vivid,  
253 dark orange-red color. The effects of inclusion of roe from various sources were  
254 apparent in the instrumental data, especially in the  $b^*$  values (yellowness) and chroma  
255 (color saturation) of the products (Table 6). The  $b^*$  value of samples (both puree and  
256 chunk) with sockeye roe (25.8) was lower than that of samples with pink roe (28.2), and  
257 both were lower than that of the control (29.9). Chroma followed a similar trend.

258 The sensory panel's perception of yellowness and cream-brown color also varied  
259 due to the inclusion of roe; samples with roe were scored significantly lower on the visual  
260 yellow intensity scale (Table 6). However, the panel did not differentiate between  
261 samples with pink versus sockeye roe with respect to visual yellow or cream-brown  
262 colors.  $L^*$  value and hue angle were inversely correlated with visual pink, yellow and  
263 cream brown colors, while  $a^*$  and  $b^*$  values were positively correlated with all visual  
264 characteristics (Table 6). The pigments in salmon eggs are heat-labile. The proteins  
265 denature at 70-80°C (Bledsoe and others, 2003). However, from these color  
266 observations, it is evident that their characteristic colors are apparent even after the  
267 disruption of cells that occurs during homogenization and the protein denaturation that  
268 occurs during thermal processing. Fibrousness differed due to the presence of roe;  
269 formulations with roe, both pink and sockeye, were almost twice as fibrous as  
270 formulations without roe (Table 6) but only about half as fibrous as the horseradish sauce  
271 used as a reference standard. The chunks contained in the formulations with pink salmon  
272 roe had higher chewiness scores (3.2) than those with sockeye roe or no roe (2.3-2.6)

273 (Table 6) but these were still very low relative to the reference standard used (baked  
274 salmon; scale location = 10).

275 Salmon flavor was stronger in samples containing roe from sockeye salmon (Table  
276 6). Samples without roe were perceived to be more bitter. Although cooked egg odor did  
277 not differ significantly among samples, those with roe had nominally higher scores than  
278 those without roe. Samples that were scored higher for cooked egg odor had low scores  
279 for bitterness ( $r=-0.94$ ; Table 7).

280 Inclusion of chunks reduced  $a^*$  (redness) and  $b^*$  values (yellowness), which  
281 reduced chromaticity and increased hue angles (Table 8). Inclusion of chunks or roe  
282 shifted the color away from the ‘true red’ character of the product. This is noteworthy  
283 since consumer evaluation during the previous study revealed that chunked products were  
284 less visually acceptable than puréed formulations (Desantos and others, 2009).

285 Salmon flavor was more intense in chunked products (Table 8). It was correlated  
286 with savory flavor ( $r=0.89$ ; Table 7), and, to a lesser extent, with chunk chewiness  
287 ( $r=0.74$ ). Chunked products were more savory than puréed products and had higher  
288 salmon flavor scores (Table 8). This outcome is supported by strong linear correlations  
289 between the scores for these characteristics (Table 7). Since chunked formulations  
290 contained more salmon than the puréed base, addition of chunks would be expected to  
291 impact the intensity of salmon odor or flavor.

292

### 293 **Storage study results**

294 There were no two- or three-way interactions ( chunk inclusion, presence of roe,  
295 and storage time) for sensory characteristics. Salmon and sweetness odor scores were

296 non-significant ( $7.3 \pm 0.2$ , and  $2.9 \pm 0.2$ , respectively; data not shown). All visual color  
297 measures differed among samples due to the presence and type of roe in the formulation.

298         Sweaty odor was most intense in fresh samples (prior to storage) and generally  
299 decreased during storage (Table 9). This sweaty odor may be due to 2, 4-heptadienal, a  
300 compound identified by Girard and Durance (2000) described as having “fishy” and  
301 “catfood” aromas. Cooked egg odor declined after two months of storage (from  $>5$  to  
302  $<3$ ) then remained constant. It was surprising that cooked egg odor was unaffected by  
303 inclusion of salmon roe. Earthy odor remained constant during the first 2 months of the  
304 study ( $>3.6$ ) then decreased to a constant level throughout the remainder of the study. The  
305 ocean odor was an attribute measured for the first time in this series of studies of salmon  
306 quality characteristics. This characteristic followed the same trend as earthy odor. Visual  
307 pink and yellow color scores were also affected by storage time. In general, visual pink  
308 color did not change until after the fifth month of storage when there was a significant  
309 increase (from 4-5 to  $>8$ ; Table 9). Visual yellow color scores increased slightly over  
310 time, but after 6 months, were still comparable with scores at the scores at the initiation  
311 of the study.

312         Storage time appeared to have the least effect on instrumentally measured color of  
313 these products (Figure 1).  $L^*$  and  $a^*$  values of samples without roe appeared to be most  
314 stable over time, while those of samples containing chunks fluctuated slightly (Figure 1).  
315  $L^*$  values of all samples remained between 67 and 70 throughout the storage period. The  
316  $a^*$  values of all samples remained between 15 and 18 throughout the storage period. The  
317  $b^*$  value of samples without roe were higher at all time periods than those of samples

318 containing roe. In addition, the b\* values of samples without roe appeared to fluctuate  
319 more (29 to 32) than those with roe (red roe, 33 to 35; pink roe, 36 to 37).

320 Correlations between visual color and instrumental color were moderate (Table  
321 10). The best correlations were observed between visual cream-brown and L\*, a\*, b\* and  
322 chroma values ( $r = -0.80, 0.75, 0.80$  and  $0.84$ , respectively).

323 TBARS values ranged between 0.1 and 0.35 mg MDA/kg. Averaging values  
324 across storage time, products made with sockeye roe had the highest TBARS values and  
325 those with pink salmon roe had the lowest (Figure 2). Chunked formulations generally  
326 had higher TBARS values ( $\sim 0.35$ ) initially but these declined over storage time. TBARS  
327 values of all samples declined after month 2 then stayed fairly constant over the  
328 remainder of the storage period. This may be because the initial cooking and retort  
329 processing of the product initiated oxidation and production of MDA which subsequently  
330 broke down to lower molecular weight compounds over time. Ortiz and others (2009)  
331 reported that TBARS of cooked, farm-raised Coho salmon (*O. kisutch*) that had been  
332 supplemented with dietary antioxidants varied from 0.5 to 0.8. They did not change  
333 significantly in the first six months of frozen storage, nor did a trained panel detect  
334 oxidized flavor.

335

336

### Conclusions

337 Adding roe to salmon baby food resulted in a lighter, less red product regardless  
338 of roe type (pink or sockeye). Formulations with roe were almost twice as fibrous as  
339 formulations without roe. Salmon flavor was stronger in samples containing roe from  
340 sockeye salmon than in that containing roe from pink salmon. Storage time had small

341 effects on sweaty, cooked egg, earthy, and ocean odors, and pink and yellow visual  
342 scores. Visual cream-brown color was well correlated with instrumental color measures.  
343 TBARS values remained low (0.1 to 0.35 mg MDA/kg) throughout 6 months of storage.
